Convolutional Neural Networks

COSC 410: Applied Machine Learning

Spring 2022

Prof. Apthorpe

Outline

- Why CNNs?
- 1D & 2D Convolutions
- Convolution hyperparameters
 - Filter size
 - Padding
 - Stride length
- Convolutional Networks (CNNs)

Motivating Tasks

Image classification

• Predict labels per image

Object Detection

Predict labels & bounding boxes

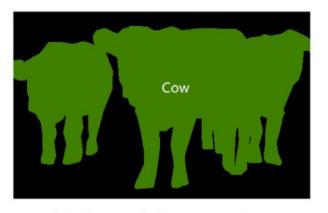

Predict labels per pixel

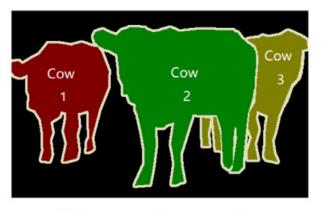

(a) Image Classification

(b) Object Detection

(c) Semantic Segmentation

(d) Instance Segmentation

Motivating Tasks

Image classification

Predict labels per image

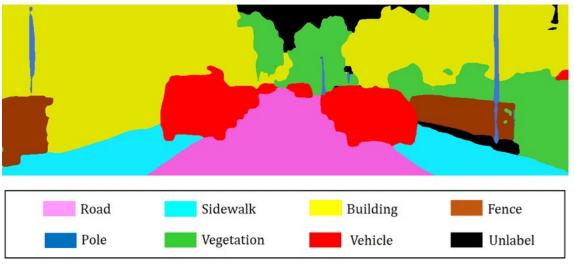

Object Detection

Predict labels & bounding boxes

Image segmentation

Predict labels per pixel

Problems with FNNs

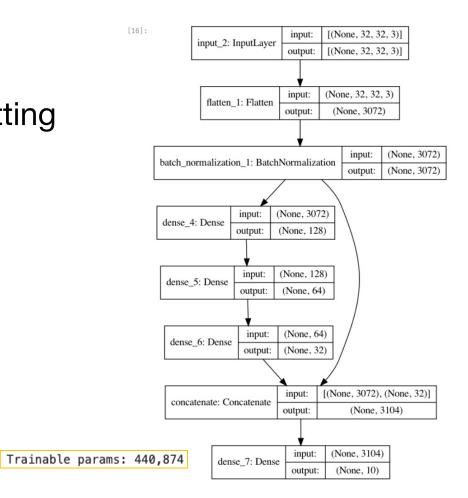

Thoughts?

Problems with FNNs

- Too many parameters
 - Even "small" FNNs are prone to overfitting

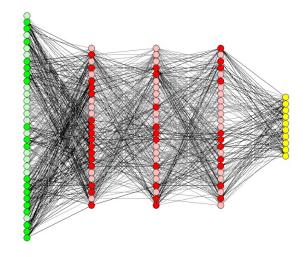

epoch_loss

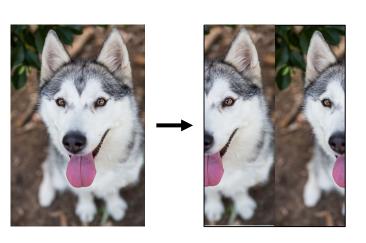

Problems with FNNs

- Does not account for feature locality
 - Assumes feature order is arbitrary
- 厚
- All features treated equivalently with respect to each other
- Sensitive to shifting data via rotation or translation

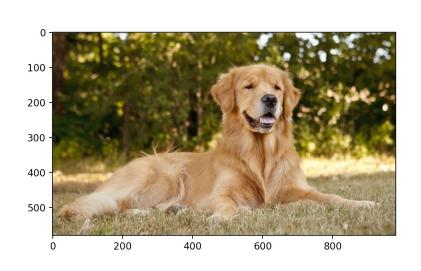

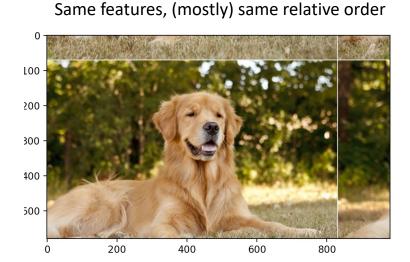

Key Ideas of CNNs

Locality

- Images encode information in the order of features
- Nearby features should be considered together

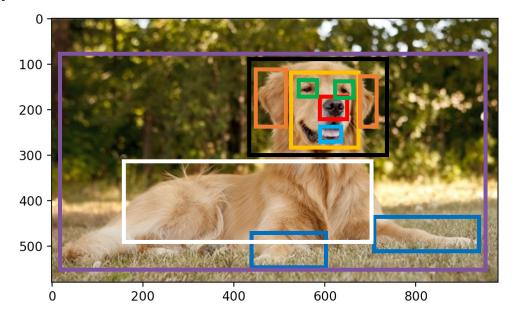

Key Ideas of CNNs

Hierarchy

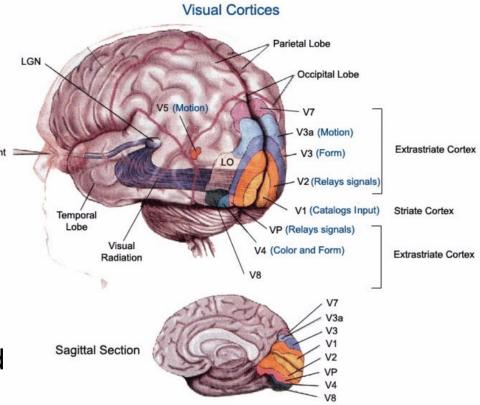

- Many data types consist of patterns of patterns
- Each layer of patterns involves a "wider" view of the data

Key Ideas of CNNs

- The human visual system is hierarchical
 - Neurons in the retina and V1 recognize simple localized light patterns
 - Neurons in higher visual cortices recognize combinations of patterns
 - Process repeats until entire scene is recognized

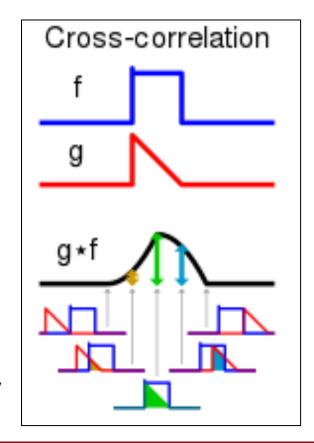

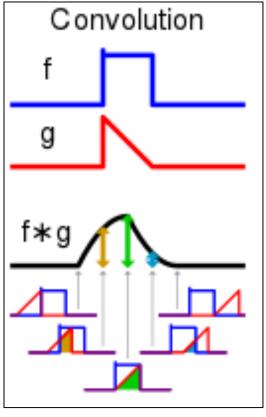

- Fewer overall parameters
- Insensitivity to data translation

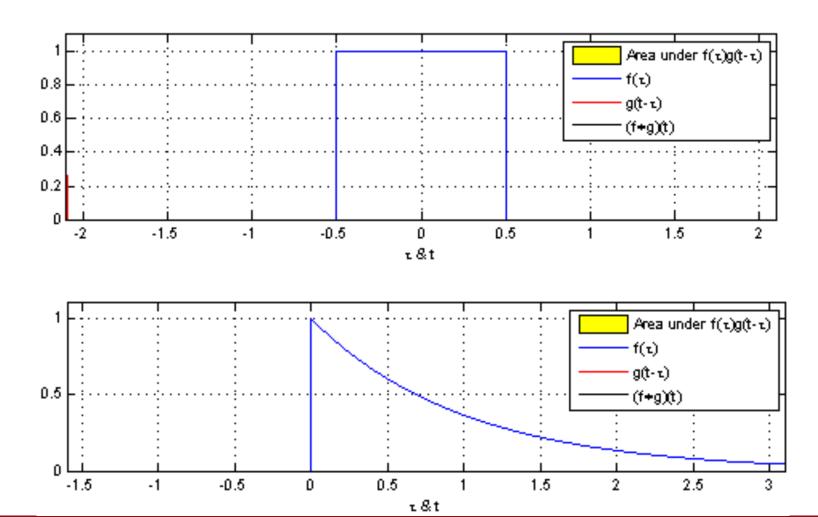

Convolutions & Cross-Correlations

- Convolution and cross-correlation are operations on functions
 - Measure similarity between two functions across their domains
 - Computed by sliding one function over the other and integrating overlap
 - Convolution is just cross-correlation with one function reflected over y-axis
 - "Convolutional" neural networks actually use cross-correlation for simplicity

1D Cross-Correlation Examples

Convolution Hyperparameters

Filter Size

- Convolutional filters identify areas of the image with similar patterns
- Why might you want larger or smaller filters?

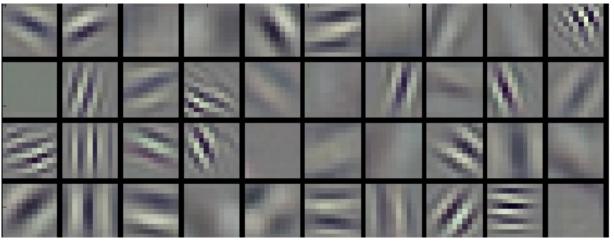

Example convolutional filters

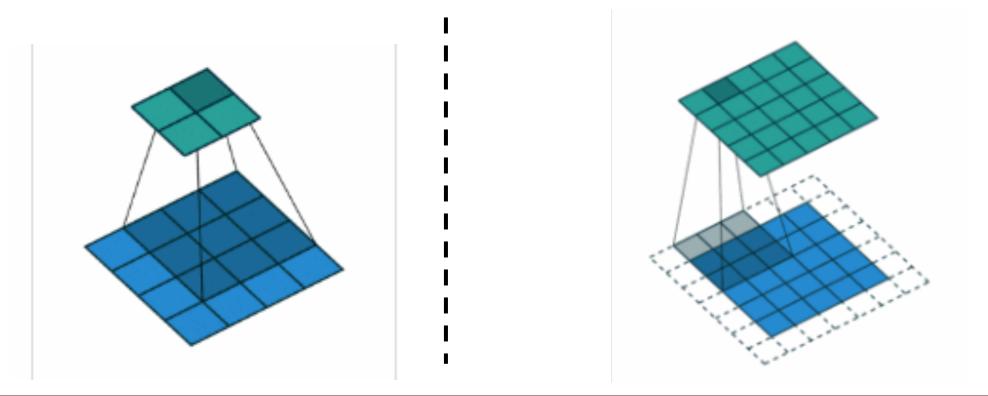

Filter Size

- Convolutional filters identify areas of the image with similar patterns
- Larger filters can identify larger patterns, but have more parameters and less locality benefit

Example convolutional filters

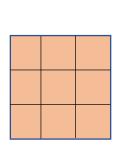

- In our convolution example, the result was smaller than the original image
- If we add padding to the edges of the input, the result will be the same size

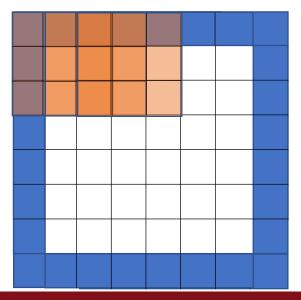

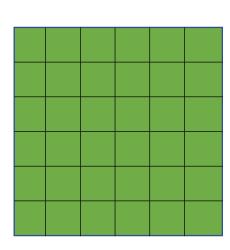

Padding options

- "Same" Add padding (usually 0s) to edges of data so convolution results are the same size as the input examples
- Width of padding depends on filter size

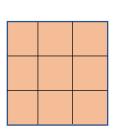

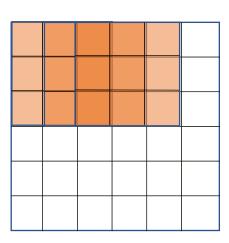

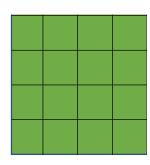

Padding options

- "Valid" Do NOT add padding, so convolution results are is smaller than the input example
- Size difference depends on filter size

• Why might you want "same" vs. "valid" padding or vice versa?

- When to use different padding options
 - "Same" (padding): Use for image segmentation when each pixel in input needs a label in the output or generally when the edges have important info

Don't cut off the edges of the scene!

- When to use different padding options
 - "Same" (padding): Use for image segmentation when each pixel in input needs a label in the output or generally when the edges have important info
 - "Valid" (NO padding): Use for image classification when you only need label(s) for the entire image or generally when the edges are irrelevant

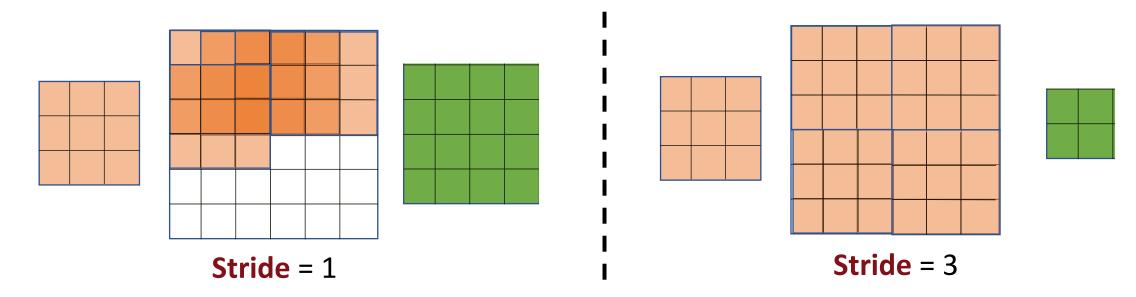

Label: Dog

Label: Cat

Stride

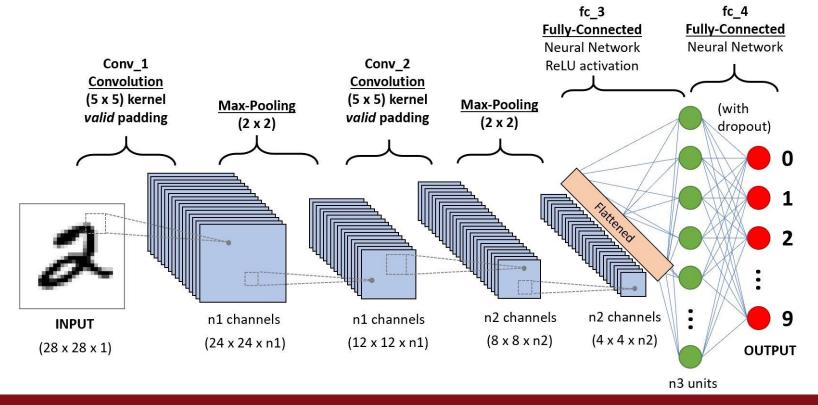

- In our 2D convolution example, we slid the filter by one "space" each time
- We can also choose to slide the filter by multiple spaces
- Tradeoff between identifying overlapping patterns & computation cost

Convolutional Neural Networks

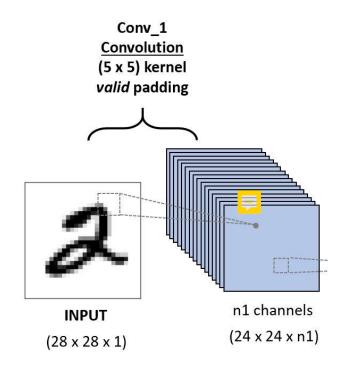

Convolutional Neural Networks (CNNs)

 Combine many convolutional filters in parallel and in sequence to identify localized & hierarchical patterns in data

Convolutional Layers

- Primary building block of CNNs
 - N independent convolutional filters
 - N is a hyperparameter
 - All filters have same size, padding, and stride
 - All filters initialized to different random starting weights
 - Activation function applied to each filter output

• Produces N unique outputs called "feature maps" for each input

Pooling Layers

Downsampling

Allows following convolution layers to find patterns over wider areas

Reduces # of computations

厚

Pros & cons

Information loss can reduce performance

Max-Pooling
(2 x 2)

n1 channels
(24 x 24 x n1)

(12 x 12 x n1)

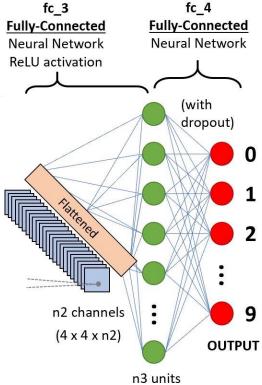

Computation is less
 of a bottleneck than it used to be

Fully Connected Layers

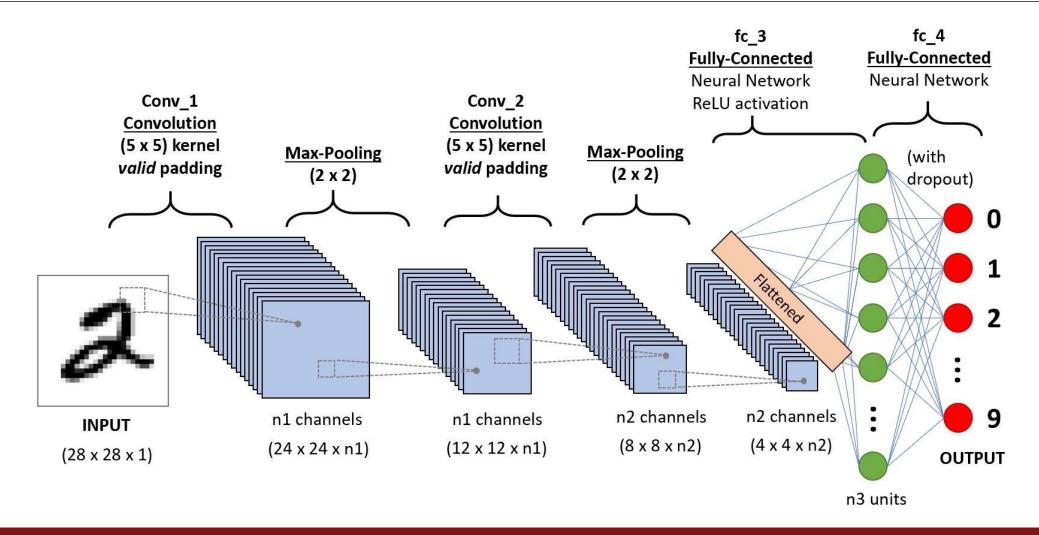

• CNNs for image classification often end with one (or more) fully-connected feedforward layers

 Effectively a FNN that treats the outputs of the last convolutional layers as input features

Produces class probabilities or regression values

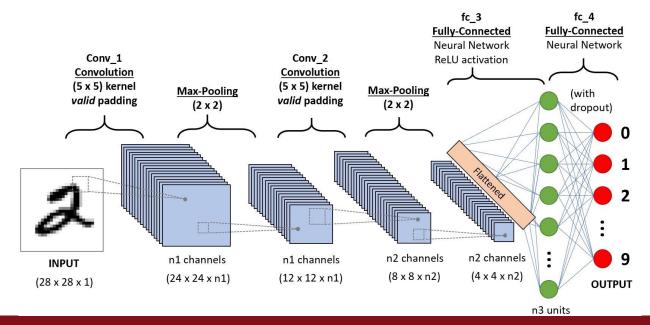

CNN Architecture

Training CNNs

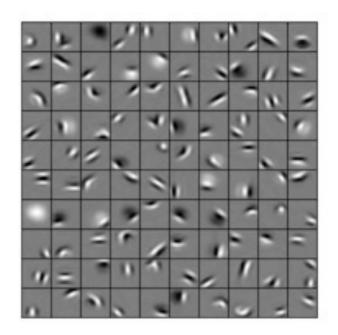

Training CNNs

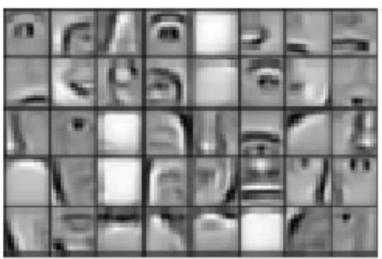

- Goal: Find convolutional filter weights (and feedforward connection weights if applicable) that minimize training error
- Approach: Gradient descent with backpropagation

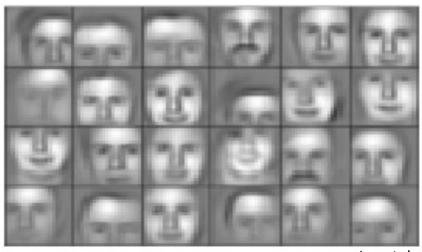

Example Trained CNN Filters

Lee, et al.

Conv layers early in network

→ Conv layers later in network
